

# Programming language theory, 2020 spring.

Start date: 24.02.2019

Deadline: 29.02.2019, 9:00 (means before lesson)

## Home work 3:

### Exercise 1. using Church Booleans:

$F = \lambda x. \lambda y. y$ ,  $T = \lambda x. \lambda y. x$

$XOR = \lambda a. \lambda b. a(bFT)(bTF)$

$NOT = \lambda a. aFT$

$AND = \lambda a. \lambda b. abF$

### Exercise 2. using Church Numerals

$pred = \lambda n. \lambda y. \lambda x. n(\lambda w. \lambda z. z(w y))(\lambda g. x)(\lambda g. g)$

$minus = \lambda p. \lambda q. (q pred)p$

$isequal = \lambda p. \lambda q. AND(GreaterOREqual(p q) GreaterOREqual(q p))$

*due to  $GreaterOREqual = \lambda p. \lambda q. isZero(p pred q)$ ,  $iszero = \lambda p. p(\lambda a. F)T$*

### Exercise 4. Implement factorial using

1) Y-combinator -  $\lambda y. (\lambda x. y(x x))$

multiplication =  $\lambda p. \lambda q. \lambda x. p(q x)$

factorial = Y-combinator  $(\lambda p. \lambda q. p(multiplication q(pred q))F)$

2) Z-combinator -  $\lambda p. (\lambda q. p(\lambda r. (q q)r))(\lambda q. p(\lambda r. (q q)r))$

factorial = Z-combinator  $(\lambda p. \lambda q. p(\lambda x. (multiplication q(pred q)F))$

I can't understand and check it by my own, so I tried to find more information about it in other sources.

$$\begin{aligned}
 Y(f) &= (g \Rightarrow (x \Rightarrow g(x(x))))(x \Rightarrow g(x(x)))(f) \\
 &= \underbrace{(x \Rightarrow f(x(x)))(x \Rightarrow f(x(x)))}_{\textcircled{1}} \\
 &= f(\underbrace{(x \Rightarrow f(x(x)))(x \Rightarrow f(x(x)))}_{\textcircled{2}}) \\
 &\quad \textcircled{1} \text{ and } \textcircled{2} \text{ are exactly the same and } \textcircled{1} \text{ is equal to } Y(f) \text{ as per first expression, therefore} \\
 &= f(Y(f))
 \end{aligned}$$

$$\begin{aligned}
 Z(f) &= (g \Rightarrow (x \Rightarrow g(v \Rightarrow x(x)(v))))(x \Rightarrow g(v \Rightarrow x(x)(v)))(f) \\
 &= \underbrace{(x \Rightarrow f(v \Rightarrow x(x)(v)))(x \Rightarrow f(v \Rightarrow x(x)(v)))}_{\textcircled{1}} \\
 &= f(v \Rightarrow \underbrace{(x \Rightarrow f(v \Rightarrow x(x)(v)))(x \Rightarrow f(v \Rightarrow x(x)(v)))}_{\textcircled{2}}(v)) \\
 &\quad \textcircled{1} \text{ and } \textcircled{2} \text{ are exactly the same and } \textcircled{1} \text{ is equal to } Z(f) \text{ as shown by the second equivalence, therefore} \\
 &= f(v \Rightarrow Z(f)(v))
 \end{aligned}$$

<https://medium.com/swlh/y-and-z-combinators-in-javascript-lambda-calculus-with-real-code-31f25be934ec>

The difference is that it introduces a function in its definition instead of a direct calculation of an expression.

$$Y = g \Rightarrow (x \Rightarrow \overbrace{g(x(x))}^a) (x \Rightarrow \overbrace{g(x(x))}^a)$$

The **a** expression in Y becomes the **b** function in Z

$$Z = g \Rightarrow (x \Rightarrow \overbrace{g(v \Rightarrow x(x)(v))}^b) (x \Rightarrow \overbrace{g(v \Rightarrow x(x)(v))}^b)$$

Comparison between Y and Z
